

- Computers belong to one of these types based on their size, processing power, number of concurrent users supported and their cost.
 - Micro or Personal Computers support only a single user, very compact in size. Processing power is increasing but still limited when shared by many programs and users, e.g., IBM PC, laptops.
 - Mini Computers (minis) More processing power can be shared among multiple users, e.g., SUN workstations. Generally, more expensive than micro computers. A network of minis used for 60-140 Dr. C.I. Ezeife © 2015 Slide 5

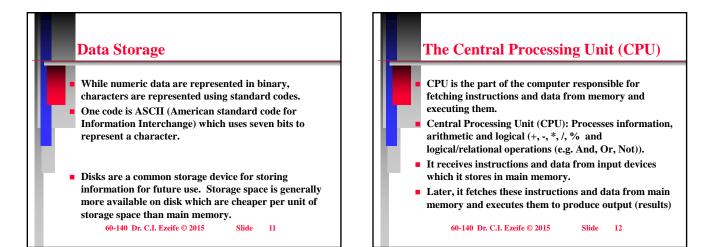

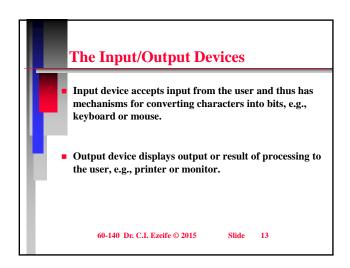

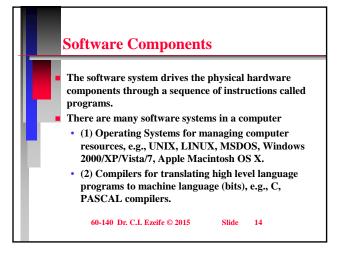

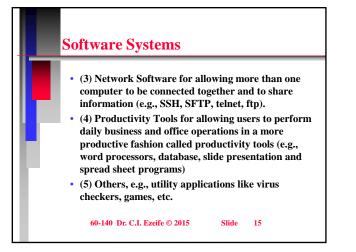

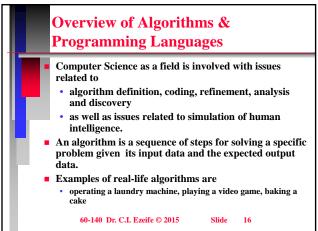

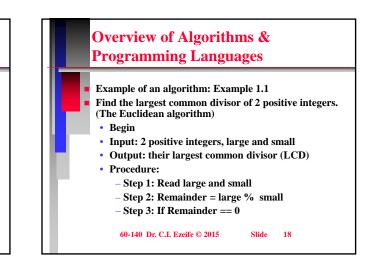

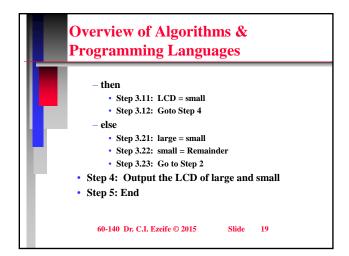

Overview of Algorithms & Programming Languages

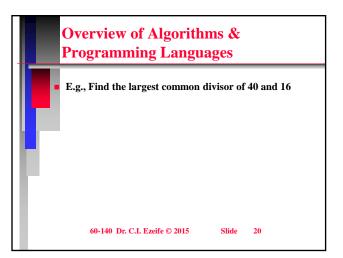

Algorithms?

- Algorithms are executed by human beings or computers. An example software for executing algorithms is RAPTOR which is available on our cs servers through NoMachine connection.
- When executed by people, an algorithm needs to be presented at their level of understanding and in a language they understand
- When executed by machine (computer), an algorithm also needs to be presented at its level of understanding and in a language it understands.

17

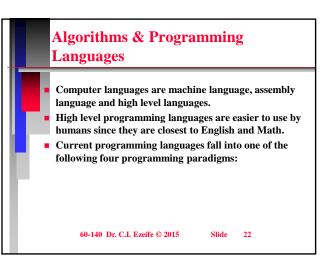

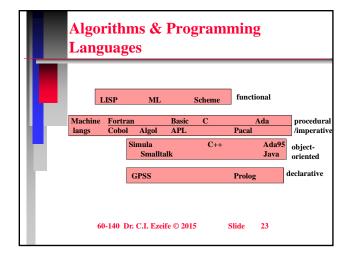

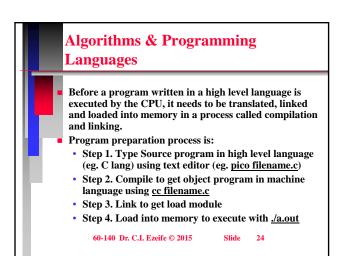

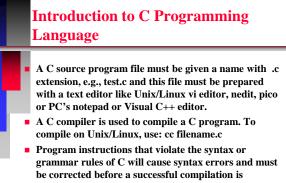

- Focus of the course (60-140) is on how to discover programs for solving a task (problem solving)
 To do this, we may need to first define the precise sequence of steps for solving this problem represented
- as an algorithm in pseudocode.The computer does not understand pseudocode but a
- program written in a computer language.Thus, for the computer to execute our algorithm, it
- eventually needs to be translated into a program in a computer language like C.

achieved.

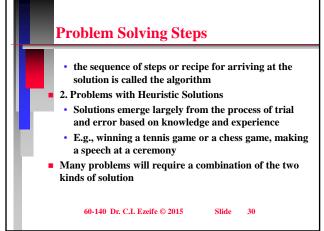

25

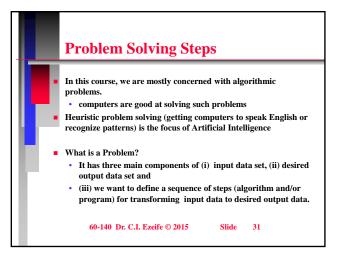

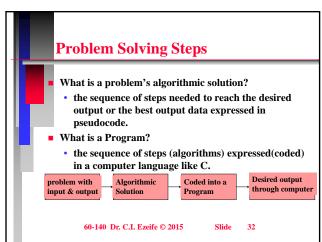

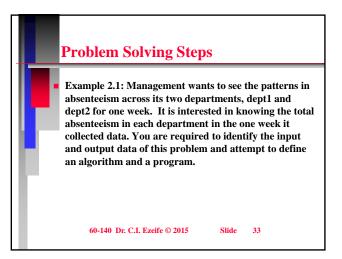

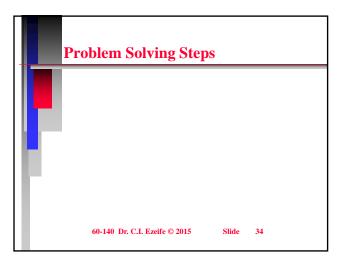

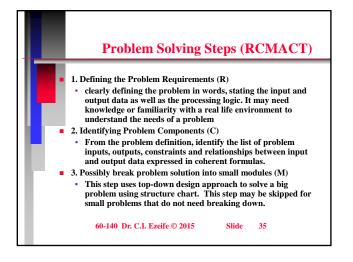

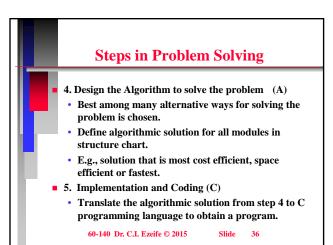

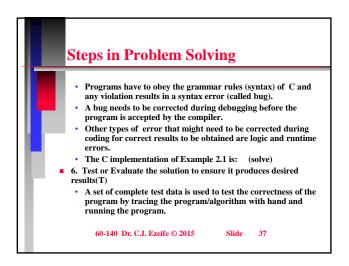

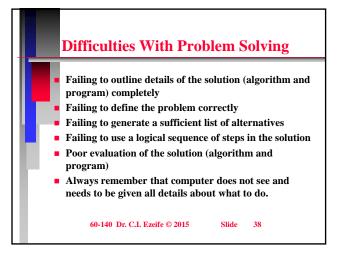

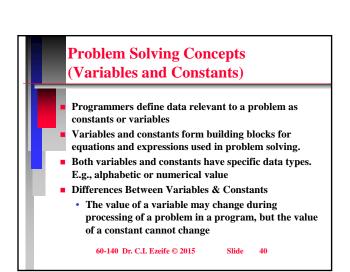

3. Types of Algorithmic and Program Instructions

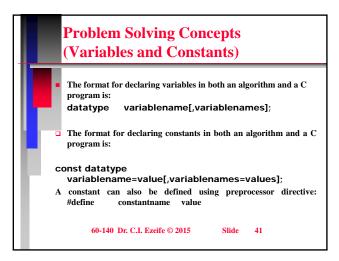

- Objectives
- 1. Introduce programming language concepts of variables, constants and their data types
- **2.** Introduce types of algorithmic and program instructions
- **3.** Discuss Read(scanf)/Print(printf) and Assignment instructions.
- Variables and Constants
- Variables and Constants are names for storage locations (memory cells) holding data values processed by the computer

Data Types		
Data Type	Data Set	Example Data
Integer(int)	All whole numbers, e.g., -2^{31} to $(2^{31}-1)$	1999, -67
Real (float/	All real numbers (whole	1999.0,
double)	+ decimal parts)	258923.61
		0.00581
Character	All letters, numbers, and	'A',`b',`K',
(char)	special symbols.	`1',`8',`+'
String(char variable[])	Combination of >1 chars.	"Atlas", "956"
Logical	TRUE FALSE	TRUE FALSE
(int with 0		
or !0)		

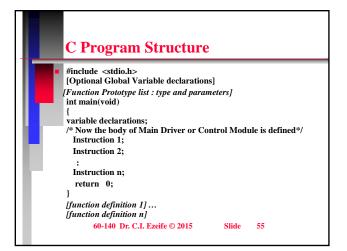

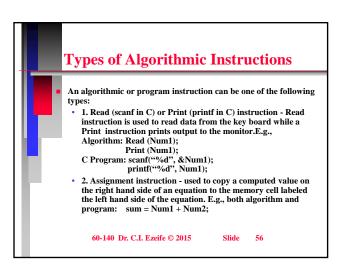

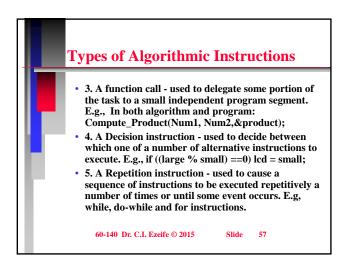

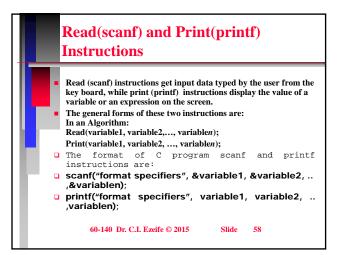

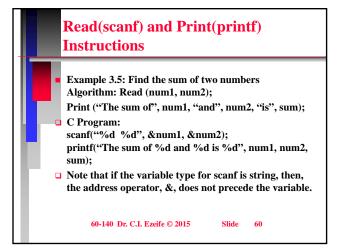

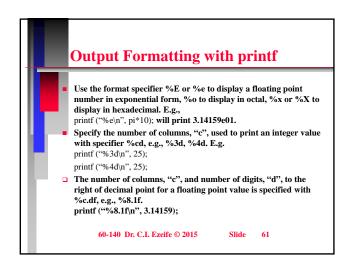

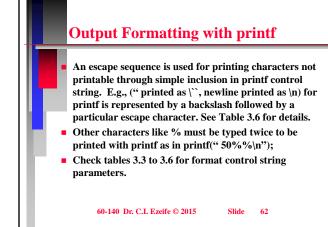

Read(scanf) and Print(printf) Instructions

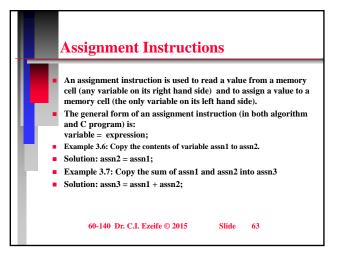

- Both scanf and printf accept a number of parameters (arguments).
- A parameter could be a variable name, an expression or a string literal, but only variable name parameters are accepted by scanf.
- Both scanf and printf have the first parameter as a string literal for format specifiers (specifying the data type of the variables or data in the parameters).
- Format specifiers for int is %d and %ld for long int, %f for float and %lf for double, %c for char and %s for string.

Precedence Hierarchy of Basic Operators in C		
■ Higest	Operator	Associativity Rule
	()	left to right
	Functions !, (-)	left to right right to left
	*, /, %	left to right
	*,/, % +,-	left to right
	<, >, <=, >=,	left to right
	==,!=	left to right
17. A State 18.	&&	left to right
Lowest	I	left to right
 Parenthesi 	is can be used to overide p	orecedence order

4. Problem Solving Tools (Top-Down Design) Objective: 1. Discuss structure chart 2. Discuss functions and algorithms with parameters, local and global variables 3. Discuss Built-in Functions and flowcharts. Top-down design approach to problem solving is based on the principle of "divide and conquer". It breaks down the problem to be solved into smaller sub-problems using the problem solving tool of structure chart

Address Operator (&), Pointer Variable and Indirection Operator (*)

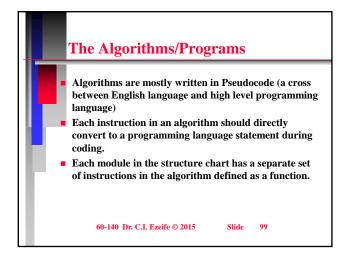

- A pointer variable stores only memory addresses
- A pointer variable has to be declared before use in a program with the format:
- datatype_pointed_to *variablename;
- E.g., if in main, Num1 is an integer variable with value 35 and Sum is another int variable with value 200.
- We might want to call a function to find the sum of Num1 and Sum with the call FindSum(Num1, &Sum).
- The actual parameter &Sum is the address of the variable Sum. This means that in the definition of
