Comp-4150: Advanced and Practical Database Systems

• Ramez Elmasri, Shamkant B. Navathe(2016) Fundamentals of Database Systems (7th Edition), Pearson, isbn 10: 0-13-397077-9; isbn-13:978-0-13-397077-7.

Chapter 14: Basics of Functional Dependencies and Normalization for Relational Databases

Review for Comp 4150 (previously discussed in Comp 3150)

Chapter 14: Basics of Functional Dependencies and Normalization for Relational Databases: Outline

- 1 Informal Design Guidelines for Relational Databases
 - 1.1 Semantics of the Relation Attributes
 - 1.2 Redundant Information in Tuples and Update Anomalies
 - 1.3 Null Values in Tuples
 - 1.4 Spurious Tuples
- 2 Functional Dependencies (FDs)
 - 2.1 Definition of Functional Dependency

Chapter 14 Outline

- 3 Normal Forms Based on Primary Keys
 - 3.1 Normalization of Relations
 - 3.2 Practical Use of Normal Forms
 - 3.3 Definitions of Keys and Attributes Participating in Keys
 - 3.4 First Normal Form
 - 3.5 Second Normal Form
 - 3.6 Third Normal Form
- 4 General Normal Form Definitions for 2NF and 3NF (For Multiple Candidate Keys)
- 5 BCNF (Boyce-Codd Normal Form)
- 6. A sample Normalized Company Database Schema
- 7 Multivalued Dependency and Fourth Normal Form
- 8 Join Dependencies and Fifth Normal Form

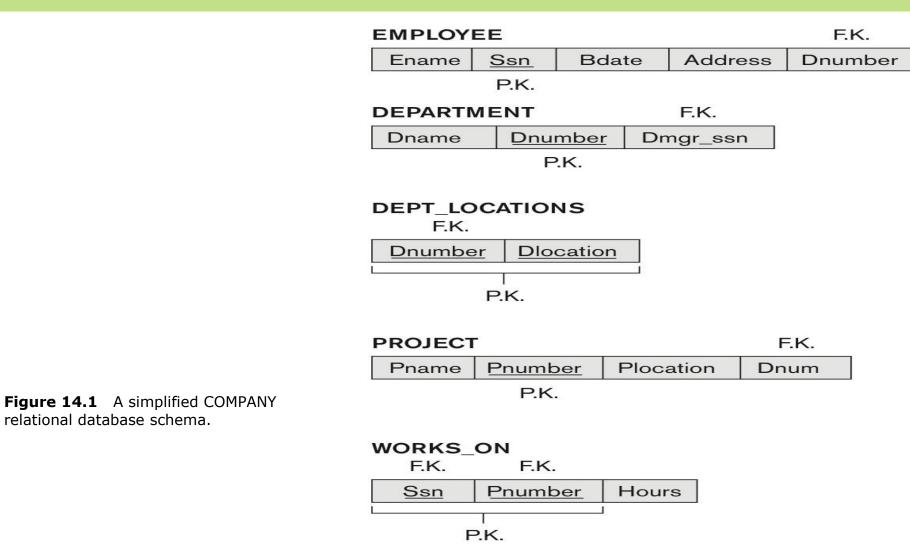

1 Informal Design Guidelines for Relational Databases

- How do we analyze database design? How do we analyze the grouping of the attributes into relations for a mini world?
- How do we measure the goodness of relation schemas.
- Relational DB design produces a set of relations with the implicit goals of information preservation and minimum redundancy.
- What are the criteria for "good" base relations?

1 Informal Design Guidelines for Relational Databases

- 1. Informal Design guidelines
 - a. Four information guidelines used to measure the quality of relation schema design are
 - i. Attributes in the schema have clear semantics
 - ii. Redundant information in tuples are reduced.
 - iii. NULL values in tuples are reduced.
 - iv. Possibility of generating spurious tuples are disallowed.
 - b. Fig 14.1 shows a simplified form of the company schema with clear meaning
 - <u>**Guideline 1:**</u> Design a relation with clear meaning and which does not combine attributes from multiple entity types such as Employee and Department.

Figure 14.1 A simplified COMPANY relational database schema

1.2 Redundant information in tuples and update anomalies

- Note that fig 14.4 is the result of applying natural join operation on Employee and Department of fig 14.2 (a database state of the schema of Fig. 14.1).
- Storing natural joins of base relations leads to update anomalies which are insertion, deletion and modification anomalies.
- Anomalies are indications of presence of redundancy in DB design.

1.2 Redundant information in tuples and update anomalies

Information is stored redundantly

- Wastes storage
- Causes problems with update anomalies
 - Insertion anomalies
 - Deletion anomalies
 - Modification anomalies

EXAMPLE OF AN UPDATE ANOMALY

- Consider the relation:
 - EMP_PROJ(Emp#, Proj#, Ename, Pname, No_hours)
- Update Anomaly:
 - Changing the name of project number P1 from "Billing" to "Customer-Accounting" may cause this update to be made for all 100 employees working on project P1.

EXAMPLE OF AN INSERT ANOMALY

- Consider the relation:
 - EMP_PROJ(<u>Emp#, Proj#, Ename, Pname, No_hours</u>)
- Insert Anomaly:
 - Cannot insert a project unless an employee is assigned to it.
- Conversely
 - Cannot insert an employee unless he/she is assigned to a project.

EXAMPLE OF A DELETE ANOMALY

- Consider the relation:
 - EMP_PROJ(<u>Emp#, Proj#, Ename, Pname, No_hours</u>)
- Delete Anomaly:
 - When a project is deleted, it may result in deleting all the employees who work on that project.
 - Alternatively, if an employee is the sole employee on a project, deleting that employee would result in deleting the corresponding project.

PT and

Sample states for EMP_DEPT and EMP_PROJ resulting from applying NATURAL JOIN to the relations in Figure 14.2. These may be stored as base relations for performance reasons.

Figure 14.4

Guideline for Redundant Information in Tuples and Update Anomalies

- GUIDELINE 2:
 - Design a schema that does not suffer from the insertion, deletion and update anomalies.
 - If there are any anomalies present, then note them so that applications can be made to take them into account.

1.3 Null Values in Tuples

• GUIDELINE 3:

- Relations should be designed such that their tuples will have as few NULL values as possible
- Attributes that are NULL frequently could be placed in separate relations (with the primary key)
- Reasons for nulls:
 - Attribute not applicable or invalid
 - Attribute value unknown (may exist)
 - Value known to exist, but unavailable

1.4 Generation of Spurious Tuples – avoid at any cost

- Bad designs for a relational database may result in erroneous results for certain JOIN operations
- The "lossless join" property is used to guarantee meaningful results for join operations
- GUIDELINE 4:
 - The relations should be designed to satisfy the lossless join condition.
 - No spurious tuples (not in the original relation) should be generated by doing a natural-join of any decomposed relations.
 - Design relation schemas that can be joined with equality conditions on attributes that are (primary key, foreign key) pairs

Spurious Tuples

- There are two important properties of decompositions:
 - a) Non-additive or losslessness of the corresponding join
 - b) Preservation of the functional dependencies.
- Note that:
 - Property (a) is extremely important and <u>cannot</u> be sacrificed.
 - Property (b) is less stringent and may be sacrificed. (See Chapter 15).

2. Functional Dependencies

- Functional dependencies (FDs)
 - FDs are used to specify *formal measures* of the "goodness" of relational designs
 - FDs and keys are used to define normal forms for relations
 - FDs are constraints that are derived from the meaning and interrelationships of the data attributes
- A set of attributes X *functionally determines* a set of attributes
 Y if the value of X determines a unique value for Y

2.1 Defining Functional Dependencies

- X → Y holds if whenever two tuples have the same value for X, they must have the same value for Y
 - For any two tuples t1 and t2 in any relation instance r(R): If t1[X]=t2[X], then t1[Y]=t2[Y]
- $X \rightarrow Y$ in R specifies a *constraint* on all relation instances r(R)
- Written as X → Y; can be displayed graphically on a relation schema as in Figures. (denoted by the arrow:).
- FDs are derived from the real-world constraints on the attributes

Examples of FD constraints (1)

- Social security number determines employee name
 SSN → ENAME
- Project number determines project name and location
 PNUMBER → {PNAME, PLOCATION}
- Employee ssn and project number determines the hours per week that the employee works on the project
 - {SSN, PNUMBER} → HOURS

Examples of FD constraints (2)

- An FD is a property of the attributes in the schema R
- The constraint must hold on every relation instance r(R)
- If K is a key of R, then K functionally determines all attributes in R
 - (since we never have two distinct tuples with t1[K]=t2[K])

Defining FDs from instances

- Note that in order to define the FDs, we need to understand the meaning of the attributes involved and the relationship between them.
- An FD is a property of the attributes in the schema R
- Given the instance (population) of a relation, all we can conclude is that an FD <u>may exist</u> between certain attributes.
- What we can definitely conclude is that certain FDs <u>do not</u> <u>exist</u> because there are tuples that show a violation of those dependencies.

Figure 14.8 What FDs may exist?

- A relation R(A, B, C, D) with its extension.
- Which FDs <u>may exist</u> in this relation?
- The following FDs may hold B->C, C->B
- The following FDs do not hold A->B, B->A, D->C
- We denote by F the set of functional dependencies specified on relation schema R.

A	В	С	D
a1	b1	c1	d1
a1	b2	c2	d2
a2	b2	c2	d3
a3	b3	c4	d3

3.1 Normalization of Relations (1)

Normalization:

 Is the process of decomposing unsatisfactory "bad" relations by breaking up their attributes into smaller relations

Normal form:

 Condition using keys and FDs of a relation to certify whether a relation schema is in a particular normal form

Normalization of Relations (2)

- 2NF, 3NF, BCNF
 - based on keys and FDs of a relation schema
- 4NF
 - based on keys, multi-valued dependencies : MVDs;
- **5NF**
 - based on keys, join dependencies : JDs
- Additional properties may be needed to ensure a good relational design (lossless join, dependency preservation; see Chapter 15)

3.2 Practical Use of Normal Forms

- Normalization is carried out in practice so that the resulting designs are of high quality and meet the desirable properties
- The practical utility of these normal forms becomes questionable when the constraints on which they are based are hard to understand or to detect
- The database designers need not normalize to the highest possible normal form
 - (usually up to 3NF and BCNF. 4NF rarely used in practice.)
- Denormalization:
 - The process of storing the join of higher normal form relations as a base relation—which is in a lower normal form

3.3 Definitions of Keys and Attributes Participating in Keys (1)

- A superkey of a relation schema R = {A1, A2, ..., An} is a set of attributes S subset-of R with the property that no two tuples t1 and t2 in any legal relation state r of R will have t1[S] = t2[S] because it contains the key K.
- A key K is a superkey with the additional property that removal of any attribute from K will cause K not to be a superkey any more.

Definitions of Keys and Attributes

- If a relation schema has more than one key, each is called a candidate key.
 - One of the candidate keys is *arbitrarily* designated to be the primary key, and the others are called secondary keys.
- A **Prime attribute** must be a member of *some* candidate key
- A Nonprime attribute is not a prime attribute—that is, it is not a member of any candidate key.

3.4 First Normal Form (1NF)

- INF states that the domain of an attribute must include only atomic (simple, indivisible) values.
- Thus, 1NF disallows
 - composite attributes
 - multivalued attributes
 - nested relations; attributes whose values for an *individual tuple* are non-atomic
- INF is considered to be part of the definition of a relation
- Most RDBMSs allow only those relations to be defined that are in First Normal Form

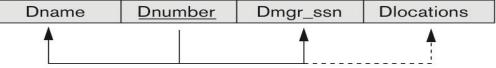

3.4 First Normal Form (1NF)

- For example, Fig 14.9b is not in 1NF
- To put in 1NF, break the fig 14.9b table into two tables:
 - Department(Dname, Dnumber, Dmgr-ssn) and
 - DEPT_LOCATIONS(Dnumber, DLocations) as in Fig 14.2 (a db state of Fig 14.1).
 - This decomposition is done by removing the attribute Dlocations that violates 1NF and placing it in a separate relation along with the primary key Dnumber of DEPARTMENT to maintain connection.
- Fig 14.10(b) has the schema EMP_PROJ(ssn, Ename {PROJS(Pnumner, Hours) })
- This relation EMP_PROJ is not in 1NF as it has nested relations as value of attribute PROJS identified in { } as multivalued.

Ssn Ename

EMP_PROJ2

Ssn	Pnumber	Hours

3.5 Second Normal Form (2NF)

- 2NF is based on the concepts of FDs, and primary key
- Definitions
 - Prime attribute: An attribute that is member of the candidate key K
 - Full functional dependency: a FD Y -> Z where removal of any attribute from Y means the FD does not hold any more (or if no proper subset of Y also determines Z).
- Examples:
 - {SSN, PNUMBER} -> HOURS is a full FD since neither SSN -> HOURS nor PNUMBER -> HOURS hold
 - {SSN, PNUMBER} -> ENAME is not a full FD (it is called a partial dependency) since SSN -> ENAME also holds
- A Relation schema R is in 2NF if every nonprime attribute (not a member of primary or candidate key) A in R is FFD (fully functionally Dependent) on the primary or candidate key of R.

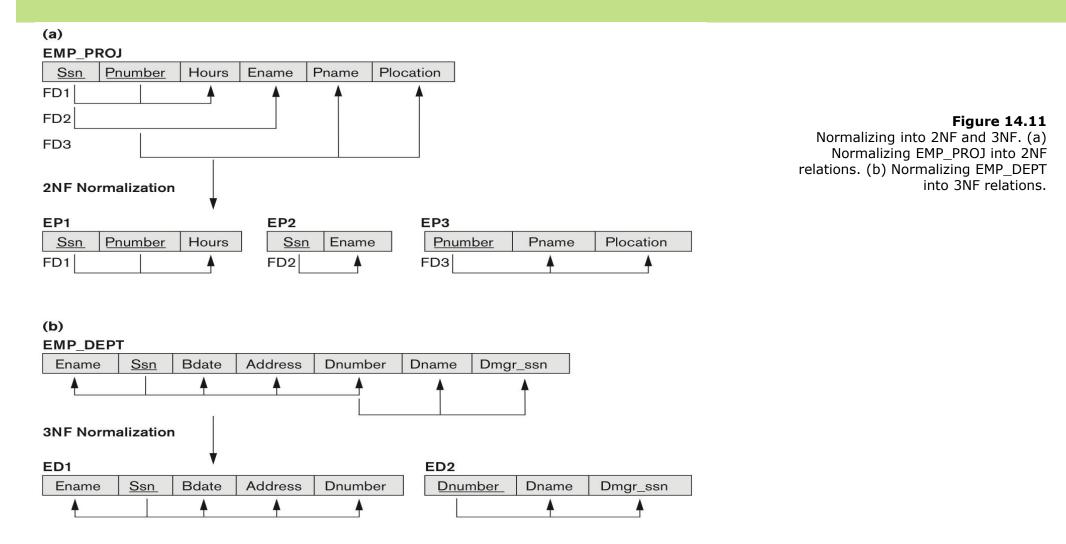

3.5 Second Normal Form (1)

- A Relation schema R is in 2NF if every nonprime attribute A in R is FFD(fully functionally Dependent) on the primary/candidate key of R.
- The Test for 2NF involves testing for FD's whose left hand side attributes are part of the primary key.
 - $\,\circ\,$ Eg. The EMP_PROJ relation of Fig 14.3 copied to Fig 14.11 is not in 2NF
 - Emp_Proj(<u>Ssn</u>, <u>Pnumber</u>, Hours, Ename, Pname, Plocation) has the following FDs
 - o FD1: (Ssn,Pnumber)->Hours
 - FD2: Ssn-> Ename
 - o FD3: Pnumber-> Pname, Plocation

3.5 Second Normal Form (2NF)

- EMP_PROJ is not in 2NF because from FD2 and FD3:
 - the nonprime (non key) attributes Ename, Pname and Plocation are determined by a subset of the primary key of EMP_PROJ(Ssn, Pnumber) thus violating the 2NF test stating that all non key attributes should be FFD on the key.
- To place in 2NF, break into a number of relations in which non key attributes are associated only with the part of the primary key on which they are FFD on.
- Thus, decomposition of EMP_PROJ into Fig 14.11(a) which are EP1, Ep2 and Ep3 in 2NF.
- EP1(<u>Ssn</u>, <u>pnumber</u>, Hours)
- Ep2(<u>Ssn</u>, Ename)
- EP3(<u>Pnumber</u>, Pname, Plocation)

Figure 14.11 Normalizing into 2NF and 3NF

3.6 Third Normal Form (3NF)

- Definition:
 - Transitive functional dependency: is a FD X -> Z that can be derived from two FDs X -> Y and Y -> Z
- Examples:
 - SSN -> DMGRSSN is a transitive FD
 - Since SSN -> DNUMBER and DNUMBER -> DMGRSSN hold
 - SSN -> ENAME is non-transitive
 - Since there is no set of attributes X where SSN -> X and X -> ENAME

Third Normal Form (2)

- A relation (R) is in 3NF if it is in 2NF and no non prime attribute of R is transitively dependent on the primary/candidate key. That is, when both of these conditions hold:
 - (a) R is fully functionally dependent on every key of R
 - (b) R is non-transitively dependent on every key of R
- In X -> Y and Y -> Z, with X as the primary key, we consider this a problem only if Y is not a candidate key.
- When Y is a candidate key, there is no problem with the transitive dependency
- E.g., Consider EMP (<u>SSN</u>, Emp#, Salary).

Here, SSN -> Emp# -> Salary and Emp# is a candidate key

Normal Forms Defined Informally

- 1st normal form
 - All attributes depend on the key and are single valued.
- 2nd normal form
 - All attributes depend on the whole key (ie, all attributes are fully functionally dependent on the whole key and there are no partial keys).
- 3rd normal form
 - All attributes depend on nothing but the key
 (ie, no attribute should depend on the key through another nonkeynattribute: no transitive dependency)

4.3 Interpreting the General Definition of Third Normal Form

- Consider the 2 conditions in the Definition of 3NF:
 - A relation schema R is in **third normal form (3NF)** if whenever a FD X \rightarrow A holds in R, then either:
 - (a) X is a superkey of R, or
 - (b) A is a prime attribute of R
- Condition (a) catches two types of violations :

- one where a proper subset of a key functionally determines a nonprime attribute. This catches 2NF violations due to non-full functional dependencies.

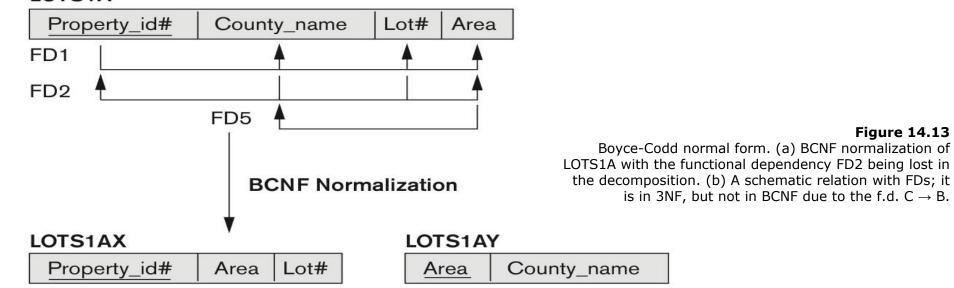

-second, where a non-prime attribute functionally determines a non-prime attribute. This catches 3NF violations due to a transitive dependency.

5. BCNF (Boyce-Codd Normal Form)

- A relation schema R is in Boyce-Codd Normal Form (BCNF) if whenever an FD X → A holds in R, then X is a superkey of R
- Each normal form is strictly stronger than the previous one
 - Every 2NF relation is in 1NF
 - Every 3NF relation is in 2NF
 - Every BCNF relation is in 3NF
- There exist relations that are in 3NF but not in BCNF
- Hence BCNF is considered a stronger form of 3NF
- The goal is to have each relation in BCNF (or 3NF)
- If there exists some FD X → A that holds in a relation schema, R where X is not a superkey (ie, a non-key attribute) and A is a prime attribute (part of the key), R will be in 3Nf but not in BCNF.

Wallace	Database	Mark
Wallace	Operating Systems	Ahamad
Wong	Database	Omiecinski
Zelaya	Database	Navathe
Narayan	Operating Systems	Ammar

Figure 14.14 A relation TEACH that is in 3NF but not BCNF.

Achieving the BCNF by Decomposition (2)

- Two FDs exist in the relation TEACH:
 - fd1: { student, course} -> instructor
 - fd2: instructor -> course
- {student, course} is a candidate key for this relation and that the dependencies shown follow the pattern in Figure 14.13 (b).
 - So this relation is in 3NF but not in BCNF
- A relation NOT in BCNF should be decomposed so as to meet this property, while possibly forgoing the preservation of all functional dependencies in the decomposed relations.
- Three possible decompositions for relation TEACH
 - D1: {<u>student, instructor</u>} and {<u>student, course</u>}
 - D2: {course, <u>instructor</u> } and {<u>course, student</u>}
 - D3: {instructor, course } and {instructor, student} ✓

7. Multivalued Dependencies and Fourth Normal Form (1)

Definition:

- A multivalued dependency (MVD) $X \longrightarrow Y$ specified on relation schema R, where X and Y are both subsets of R, specifies the following constraint on any relation state r of R: If two tuples t_1 and t_2 exist in r such that $t_1[X] = t_2[X]$, then two tuples t_3 and t_4 should also exist in r with the following properties, where we use Z to denote (R_2 ($X \cup Y$)):
 - $t_3[X] = t_4[X] = t_1[X] = t_2[X].$
 - $t_3[Y] = t_1[Y]$ and $t_4[Y] = t_2[Y]$.
 - $t_3[Z] = t_2[Z]$ and $t_4[Z] = t_1[Z]$.
- An MVD X \longrightarrow Y in R is called a **trivial MVD** if (a) Y is a subset of X, or (b) X \cup Y = R.

Multivalued Dependencies and Fourth Normal Form (3)

Definition:

- A relation schema R is in **4NF** with respect to a set of dependencies F (that includes functional dependencies and multivalued dependencies) if, for every *nontrivial* multivalued dependency $X \longrightarrow Y$ in F^+ , X is a superkey for R.
 - Note: F⁺ is the (complete) set of all dependencies (functional or multivalued) that will hold in every relation state r of R that satisfies F. It is also called the closure of F.

Figure 14.15 Fourth and fifth normal forms.

(a) EMP

<u>Ename</u>	Pname	Dname
Smith	Х	John
Smith	Y	Anna
Smith	Х	Anna
Smith	Y	John

(b) EMP_PROJECTS EMP_DEPENDENTS

Ename	Pname	Ename	Dname

Nut	ProjY
Bolt	ProjY
Nut	ProjZ
Nail	ProjX

Figure 14.15

Fourth and fifth normal forms. (a) The EMP relation with two MVDs: Ename ->> Pname and Ename ->> Dname. (b) Decomposing the EMP relation into two 4NF relations EMP_PROJECTS and EMP_DEPENDENTS. (c) The relation SUPPLY with no MVDs is in 4NF but not in 5NF if it has the JD(R1, R2, R3). (d) Decomposing the relation SUPPLY into the 5NF relations R1, R2, R3.

6. Join Dependencies and Fifth Normal Form (1)

Definition:

- A **join dependency** (**JD**), denoted by $JD(R_1, R_2, ..., R_n)$, specified on relation schema *R*, specifies a constraint on the states *r* of *R*.
 - The constraint states that every legal state r of R should have a non-additive join decomposition into $R_1, R_2, ..., R_n$; that is, for every such r we have

• *
$$(\pi_{R_1}(r), \pi_{R_2}(r), ..., \pi_{R_n}(r)) = r$$

Note: an MVD is a special case of a JD where n = 2.

• A join dependency $JD(R_1, R_2, ..., R_n)$, specified on relation schema R_i is a **trivial JD** if one of the relation schemas R_i in $JD(R_1, R_2, ..., R_n)$ is equal to R_i .

Join Dependencies and Fifth Normal Form (2)

Definition:

- A relation schema *R* is in **fifth normal form (5NF)** (or **Project-Join Normal Form (PJNF)**) with respect to a set *F* of functional, multivalued, and join dependencies if,
 - for every nontrivial join dependency $JD(R_1, R_2, ..., R_n)$ in F^+ (that is, implied by F),
 - every R_i is a superkey of R.
- Discovering join dependencies in practical databases with hundreds of relations is next to impossible. Therefore, 5NF is rarely used in practice.

Chapter Summary

- Informal Design Guidelines for Relational Databases
- Functional Dependencies (FDs)
- Normal Forms (1NF, 2NF, 3NF)Based on Primary Keys
- 1st normal form
 - All attributes depend on the key and are single valued.
- 2nd normal form
 - All attributes depend on the whole key (ie, all attributes are fully functionally dependent on the whole key and there are no partial keys).
- 3rd normal form
 - All attributes depend on nothing but the key (ie, no attribute should depend on the key through another non-keynattribute: no transitive dependency)
- BCNF :No non-key attribute determines part of candidate key
- Fourth Normal Form: ie, for every nontrivial multivalued dependency X —>> Y in F⁺, X is a superkey for R.
- Fifth Normal Form: ie, for every nontrivial join dependency JD(R1, R2, ..., Rn) in F+ (that is, implied by F), every Ri is a superkey of R.
